

COMP2113 / ENGG1340, Assignment 1

Due Date: Oct 21, 2021, 23:59

If you have any questions, please post to the Moodle discussion forum on Assignment 1.

- [General Instructions](#)
- [Problem 1: Random Number Generation](#) (20 marks)
- [Problem 2: Polynomial Evaluation](#) (15 marks)
- [Problem 3: Sine Function Approximation](#) (20 marks)
- [Problem 4: Caesar Shifting](#) (20 marks)
- [Problem 5: Bounding Boxes](#) (20 marks)

Total marks: 100 marks

- 5 marks for proper code comments and indentation
- 95 marks for program correctness

A maximum of 5 marks will be deducted if you fail to follow the submission instructions strictly.

General Instructions

Read the instructions in this document carefully.

In this assignment you will solve 5 tasks and a tester would automatically test your submitted program. So if your submitted files and program outputs do not conform to our instructions given here, your programs cannot be evaluated and you will risk losing marks totally.

Sample test cases are provided with each task in this document. Note that the test cases may or may not cover all boundary cases for the problem. It is also part of the assessment whether you are able to design proper test cases to verify the correctness of your program. We will also use additional test cases when marking your assignment submission.

Input and output format

Your C++ programs should read from the **standard input**. Also, your answer should be printed through the **standard output**. If you failed to follow this guide,

the tester may not be able to give a score for your program. Additionally, you should strictly follow the sample output format (including space, line breaker, etc.), otherwise, your answer might be considered as wrong.

How to use the sample test cases

Sample test cases in text file formats are made available for you to check against your work. Here's how you may use the sample test cases. Take Problem 2 test case 3 as an example. The sample input and the expected output are given in the files `input2_3.txt` and `output2_3.txt`, respectively. Suppose that your program is named "2", do the followings at the command prompt of the terminal to check if there is any difference between your output and the expected output.

```
./2 < input2_3.txt > myoutput.txt  
diff myoutput.txt output2_3.txt
```

Testing against the sample test cases is important to avoid making formatting mistakes. The additional test cases for grading your work will be of the same formats as the sample test cases.

Coding environment

Except Problem 1, you must make sure that your program can compile, execute and generate the required outputs on our standard environment, namely, the gcc C++11 environment we have on the CS Linux servers (academy*). Make sure the following compilation command is used to compile your programs:

```
g++ -pedantic-errors -std=c++11 [yourprogram].cpp
```

As a programmer/developer, you should always ensure that your code can work perfectly as expected on a target (e.g., your client's) environment, not only on yours.

While you may develop your work on your own environment, you should always try your program (compile & execute & check results) on our standard environment before submission.

Submission

Name your C++ programs as the following table shows and put them together into one directory. Make sure that the folder contains only these source files (*.cpp) and no other files. **Compress this directory as a [uid].zip file where [uid] is your university number** and check carefully that the correct file have been submitted. We suggest you to download your submitted file from Moodle, extract them, and check for correctness. **You will risk receiving 0 marks for this assignment if you submit incorrect files.** Resubmission after the deadline is not allowed.

Filename	Description
1.sh	Problem 1
2.cpp	Problem 2
3.cpp	Problem 3
4.cpp	Problem 4
5.cpp	Problem 5

Late submission

If submit within 3 days after the deadline, 50% deduction. After that, no mark.

Evaluation

Your code will be auto-graded for technical correctness. In principle, we use test cases to benchmark your solution, and you may get zero marks for not being able to pass any of the test cases. Normally partial credits will not be given for incomplete solution, as in many cases the logic of the programs are not complete and an objective assessment could be difficult. However, your work may still be considered on a case-by-case basis during the rebuttal stage.

Academic dishonesty

We will be checking your code against other submissions in the class and from the Internet for logical redundancy. Please be reminded that no matter whether it is providing your work to others, assisting others to copy, or copying others will all be considered as committing plagiarism and we will follow the departmental policy to handle such cases. Please refer to the course information notes for details.

Getting help

You are not alone! If you find yourself stuck on something, post your questions to the course forum, send us emails or come to our support sessions. We want this assignment to be rewarding and instructional, not frustrating and demoralizing. But we don't know when or how to help unless you ask.

Discussion forum

Please be careful not to post spoilers. Please don't post any code that is directly related to the assignments. However you are welcome and encouraged to discuss general ideas on the discussion forums. If you have any questions about this assignment you should post them in the discussion forums.

Problem 1: Random Number Generation

Suppose you have a C++ program named "random.cpp". It takes three integers a, b, and c as input, and then generates c random integers in range [a, b].

```
#include <iostream>
#include <stdlib.h>
#include <time.h>
using namespace std;
int main(){
    srand (time(NULL));
    int a,b,c,threshold;
    cin >> a >> b >> c;
    for (int i = 0 ; i < c ; i++) {
        int value = rand() % abs(b-a+1) + min(a,b);
        cout << value << endl;
    }
    return 0;
}
```

The second file is a text file named *input.txt*, which only contains a line of text as follows.

a b c

./random < input.txt > output.txt

You can assume that *random.cpp*, *input.txt* and *1.sh* are in the same directory. Your task is to write a shell script named *1.sh*. If we run it using “./1.sh d”, where d is an integer ($a \leq d \leq b$).

- (1) the script can compile *random.cpp*;
- (2) the script runs the executable with the content in *input.txt* as input;
- (3) the output should be put into a file named *output.txt*, in which each line contains a single value;
- (4) print the total number of integers whose values are at least d.

*The name of your shell file must be *1.sh*.

*You can download *random.cpp* from Moodle.

Sample Test Cases:

1_1

Content of *input.txt*:

1 10 5

After running “./1.sh 6”, content of *output.txt*:

9

2

8

8

8

Screen output:

4

1_2

Content of *input.txt*:

10 50 4

After running “./1.sh 20”, content of *output.txt*:

21

13

13

40

Screen output:

2

1_3

Content of *input.txt*:

1 100 10

After running `./1.sh 50`, content of *output.txt*:

20
21
9
19
89
86
74
99
57
3

Screen output:

5

Notice that:

- (1) In above sample, the content of “output.txt” may not be unique;
- (2) the values of a, b, c and d in the test case are different with these in above sample.

Problem 2: Polynomial Evaluation

Write a C++ program that evaluate a degree- n polynomial

$$a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$$

with n multiplications and n additions only. Note that this is the optimal, meaning that you cannot do this evaluation with fewer arithmetic operations.

Implement the [Horner's method](https://en.wikipedia.org/wiki/Horner%27s_method)

(https://en.wikipedia.org/wiki/Horner%27s_method) to achieve this optimal computation.

Input:

- A single line containing $n + 3$ numbers, separated by spaces. The first number is the value of x , then the degree n of the polynomial to evaluate, followed by the $n + 1$ coefficients a_n, a_{n-1}, \dots, a_0 .

- The value x is a floating-point number and the numbers n , a_n , a_{n-1} , ..., a_0 are integers, and $n \geq 0$.

Output:

- A single line containing the result of the polynomial evaluation, printed as a fixed floating number with 6 decimal places.
- You may use `setprecision(n)` defined in the header `<iomanip>` to set the precision parameter of the output stream.

Requirement:

- Use the `float` data type for all floating point computations in this program.
- You can ONLY use the simple data types `char`, `bool`, `int`, `float`. In other words, you are not allowed the use other data types or data structures such as arrays, vectors, etc.
-

Sample Test Cases:

User inputs are shown in blue.

2_4

-0.0001 10 11 -10 9 -8 7 -6 5 -4 3 -2 1

1.000200

Problem 3: Sine Function Approximation

Write a C++ program which calculates an estimation of $\sin x$ using Taylor series approximation with the formula:

$$\sin x = \sum_{i=0}^n \frac{(-1)^i}{(2i+1)!} x^{2i+1}$$

where $i! = 1 \times 2 \times 3 \times \dots \times i$ denote the factorial of i , and 0^0 is defined as 1. The integer n governs the order of approximation and you may assume that n ranges from 0 to 50 inclusively in this question.

Input:

- A line with two numbers: a real number x ($-3 \leq x \leq 3$) followed by an integer n ($0 \leq n \leq 50$).

Output:

Your program should output the estimations of $\sin x$ as n increases. Specifically, your program should do the following.

- On the first line, print the result of $\sin x$ as returned by the predefined function `sin()` in `<cmath>` as a fixed floating number with 15 decimal places.
- Output the values of n and $\sin x$ on the subsequent lines as n increases. The values n and $\sin x$ on each line are separated by a space. **The value $\sin x$ is printed as a fixed floating number with 5 decimal places.**
- You may use `setprecision(n)` defined in the header `<iomanip>` to set the precision parameter of the output stream.

Requirement:

- Use only the `double` and `int` data types in your calculations.
- You can ONLY use the simple data types `char`, `bool`, `int`, `double`. In other words, you are not allowed the use other data types or data structures such as strings, arrays, vectors, etc.

Note:

- You cannot evaluate the factorial operator in a brute-force manner using multiplications only, because **overflow** can easily occur which means that

- the resulting value is too large to be stored in an `int`. (Consider $30! \approx 2.6525e+32$ which cannot be held by even the `unsigned long long` type).
- Divisions involving some large numbers can easily run into numerical inaccuracy issues (you will learn more about this in the machine organization course).
 - Hence, **you should do divisions before multiplications (whenever possible) to keep the intermediate values at each iteration of the calculation small.**
 - Since different orders of arithmetic operations may entail slight difference in the final evaluation, **your results will be checked against the test outputs for correctness up to the first 5 decimal points only.**

Problem 4: Caesar Shifting

Write a C++ program which encrypts and decrypts some input characters using the Caesar Shifting algorithm detailed below.

Input:

- A line of input $s\ k\ c_1\ c_2\ c_3\ \dots$, where
 - s is either the character **e** for encryption, or the character **d** for decryption
 - k is an integer for the number of shifts used in the Caesar shift algorithm (key for encryption or decryption)
 - $c_1\ c_2\ c_3\ \dots$ is a sequence of space separated characters, ended by **!**, to be encrypted or decrypted

Output:

- The encrypted/decrypted message ended by **!**. No space between two consecutive characters.

Algorithm:

To encrypt (decrypt) a letter c (within the alphabet A-Z or a-z) with a shift of k positions:

1. Let x be c 's position in the alphabet (0 based), e.g., position of **B** is 1 and position of **g** is 6.
2. For encryption, calculate $y = x + k$ modulo 26;
For decryption, calculate $y = x - k$ modulo 26.
Here modulo is equivalent to remainder in mathematics.
3. Let w be the letter corresponding to position y in the alphabet. If c is in uppercase, the encrypted (decrypted) letter is w in lowercase; otherwise, the encrypted (decrypted) letter is w in uppercase.

A character which is not within the alphabet A-Z or a-z will remain unchanged under encryption or decryption.

Example. Given letter **B** and $k = 3$, we have $x = 1$, $y = 1 + 3 \bmod 26 = 4$, and $w = \text{E}$. As **B** is in uppercase, the encrypted letter is **e**.

Requirement:

- Implement a function `CasesarShift()` which takes in a `char c` and an `int k`, where `c` is the character to undergo Caesar Shifting and `k` is the number

- of positions (can be negative) to shift, and return the processed `char` after Caesar Shifting. The function prototype is given by:
`char CaesarShift(char c, int k)`
- You can ONLY use the simple data types `char`, `bool`, `int`, `double`. In other words, you are not allowed the use other data types or data structures such as strings, arrays, vectors, etc.

Sample Test Cases:

Problem 5: Bounding Boxes

Write a C++ program to compute a **minimum-sized** axis-aligned bounding box (AABB) for a set of input 2D geometries. An AABB is a rectangle with sides parallel to the x-, y-axes which encloses some given geometries. The input and output of your program are as follows:

Input: Each line of the user input begins with a character indicating the type of geometry, followed by some parameters of the geometric object. The input line can be one of the followings:

- **R** *x y width height*
where **R** represents an input rectangle, *x*, *y* are floating-point numbers for the x-, y-coordinates of the rectangle center, *width* and *height* are floating-point numbers for the rectangle size along the x- and y-axes, respectively.
- **C** *x y radius*
where **C** represents an input circle, *x*, *y* are floating-point numbers for the x-, y-coordinates of the circle center, and *radius* is a floating-point number for the radius of the center
- **P** *n x₁ y₁ x₂ y₂ ... x_n y_n*
where **P** represents an input point set, *n* is an integer indicating the number of points in the set, and *x_i*, *y_i*, *i* = 1, ..., *n* are floating point numbers for the x-, y-coordinates of the *n* points
- **#**
indicates end of input

Output:

- A single line
x y width height
where *x* and *y* are floating-point numbers for the x-, y-coordinates of the center of the minimum-sized AABB, *width* and *height* are floating-point numbers giving the sizes of the AABB along the x-, y-axes, respectively.

Requirement:

- Use the **double** data type for floating point calculations.
- Implement the functions

RectangleBB(), **CircleBB()** and **PointSetBB()** which take user inputs and calculate the corresponding bounding boxes of the different geometries (rectangles, circles & point sets). The function prototypes are:
void RectangleBB(double &xmin, double &xmax, double &ymin, double &ymax)
void CircleBB(double &xmin, double &xmax, double &ymin, double &ymax)
void PointSetBB(double &xmin, double &xmax, double &ymin, double &ymax)
where **xmin**, **xmax**, **ymin**, **ymax** are the calculated extends of the bounding boxes for the geometry. Note that these parameters are pass-by-reference, since they are the computation results with we would like the calling function

- to be able to access after function termination. By using pass-by-reference, the functions would be able to modify the actual arguments passed in from the calling function.
- You can ONLY use the simple data types `char`, `bool`, `int`, `double`. In other words, you are not allowed the use other data types or data structures such as strings, arrays, vectors, etc.

Note:

- The questions assume no bound for the floating-point parameters (*x*, *y*, *width*, *height*, *radius*) of the input geometries and therefore they can be any values that a double data type can hold. You may use `std::numeric_limits<double>::lowest()` and `std::numeric_limits<double>::max()` defined in the header `<limits>` in your program to obtain the smallest and the largest possible values, respectively, for the double data type.

Sample Test Cases:

User inputs are shown in blue.
